

Data Flow Architecture

This explains the technical movement of data through your Salesforce environment.

- **Input Layer:** The [Agentforce AI](#) acts as the primary data ingestion point, capturing unstructured text and converting it into structured data fields.
- **Transformation Layer:** The captured data passes through [Salesforce Flow Builder](#) logic. Here, complex business rules are applied to sanitize inputs and map them against established custom fields, ensuring that the CRM schema is strictly followed.
- **Processing Layer:** The system calculates scores by evaluating field values against predefined logic gates (e.g., scoring higher if a lead has a specific title or verified email). This scoring occurs asynchronously, allowing for massive lead volumes without impacting user performance.
- **Output Layer:** The final output is a fully qualified Lead record assigned to the relevant sales queue or user. The architecture supports full audit logs (documented in your [UAT testing screenshots](#)) to ensure that the journey from raw lead to assigned lead is transparent and repeatable.
